## Source code

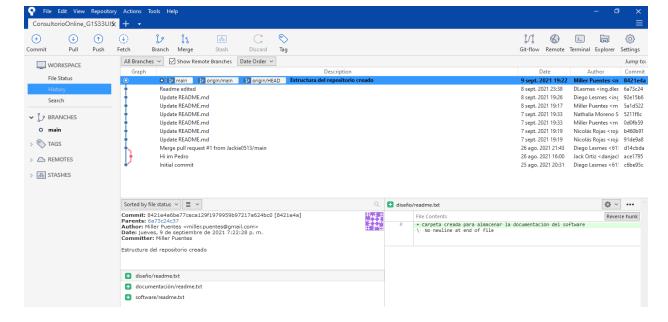

## **Work branches**

## **Conflicts resolution**

During the life cycle of a team-driven software project, team members will probably have the need to make changes to the same source code file at the same time. A VCS monitors and assists in conflicts between multiple developers. These conflict resolution operations leave an audit trail that provides information about the history of a project.

"https://bitbucket.org/product/es/version-control-software"

#### Conflict

Consultorio Privado

A conflict occurs when the system cannot adequately handle changes made by two or more users to the same file. For example, if this sequence of circumstances occurs:

- 1. The users X and Y deploy versions of the file A which lines n1 until n2 are common.
- 2. The user X sends changes between lines n1 and n2 on the file A.
- 3. The user Y doesn't update the file A later than the user X sends it.
- 4. The user Y makes changes between lines n1 and n2.
- 5. The user Y tries later to send these changes to the file A.

The system is unable to merge the changes. User Y must resolve the conflict by combining the changes, or choosing one of them to discard the other.

#### "https://es.wikipedia.org/wiki/Control\_de\_versiones"

In the software development area, having a version control tool that allows the registration of the modifications that have been made to the programs or documents, and that provides the previous versions of the software, can avoid conflicts when generating a final product.

A conflict occurs when two or more people try to make different changes to the same piece of code. All version control systems detect these conflicts automatically and notify at least one of the humans involved that their changes conflict with someone else's. It is then their job to resolve the conflict and communicate this resolution to the version control system. Git's ability to resolve conflicts is very useful, but conflict resolution takes time and effort, and can introduce errors if the conflicts are not solved correctly. If you find yourself resolving many conflicts in a project, keep these technical approaches in mind to reduce them:

- Make a pull with a higher frequent, especially before start a new task
- Use thematic branches to separate work, joining the main branch master- when they are complete
- Make short comments and concise
- When appropriate, split large files into several smaller ones so that two authors are less likely to alter the same file simultaneously

Conflicts can also be minimized with project management strategies:

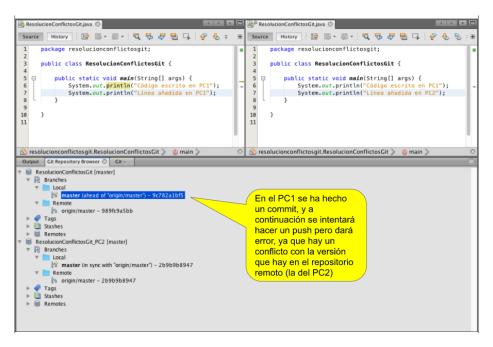

- Clarify with your collaborators who's the responsible for each area
- Discuss with your collaborators in what order the tasks should be performed so that tasks that can change the same lines are not worked simultaneously.
- If the conflicts are in style (e.g. tabs vs. spaces), establish a convention that governs the project and use code style tools

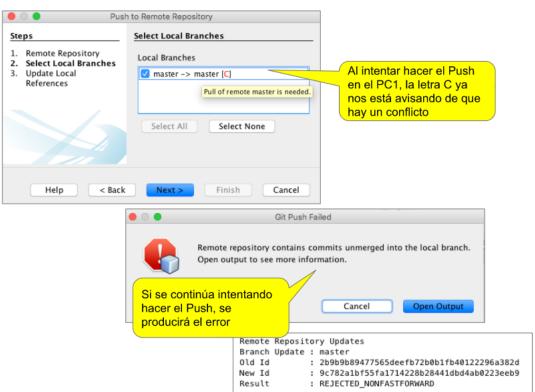

#### Example:

GIT Conflict resolution from NETBEANS

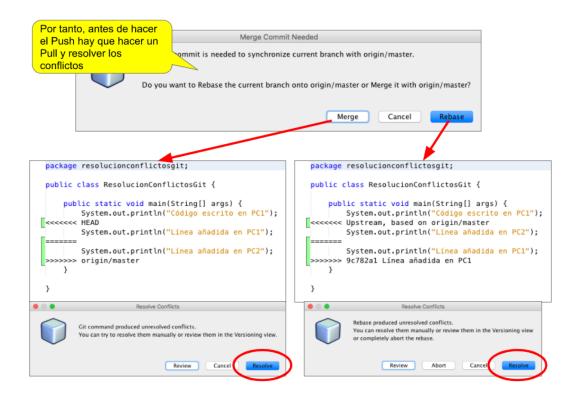

Consultorio Privado

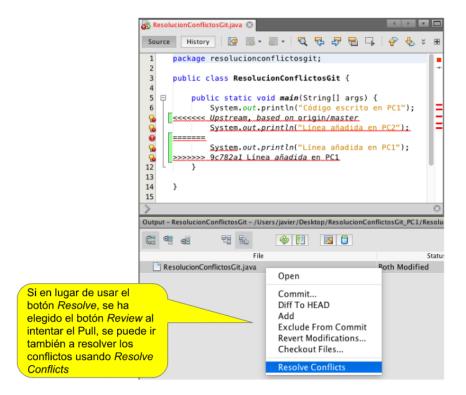

#### Consultorio Privado

Consultorio Privado

"https://javiergarciaescobedo.es/cvs-sistemas-de-control-de-versiones/99-git/413-resolucion-de-conflictos-en-git-desde-netbeans"

Conflict management is a very important part of any VCS, not only because of its resolution capacity, but also because of the ability to detect them. If a VCS does not detect a conflict, it can introduce code corruption, the results of which are often problematic. On detecting a conflict that the VCS cannot resolve automatically, the user is informed and is expected to be resolved by hand or with one of the tools designed to assist in resolving these issues. Fortunately, most modern VCS are very focused on this problem and have very good conflict detection and resolution algorithms.
